Received: December 26, 2006; In Final Form: March 13, 2007

This study investigates the adsorption and reactions of boron trichloride and its fragments ( $\text{BCl}_x$ ) on the  $\text{TiO}_2$  anatase (101) and rutile (110) surfaces by first-principles calculations. The results show that the possible adsorbates on the  $\text{TiO}_2$  anatase and rutile surfaces are very similar. The single- and double-site adsorption configurations are found for both anatase and rutile surfaces. The particular adsorbate feature on the anatase surface is its in-plane double-site adsorption by Ti and O from its sawtooth surface. The potential energy surface shows that  $\text{BCl}_3$  can be adsorbed on the O site for both the anatase and rutile surfaces and the most of the  $\text{BCl}_x$  reaction on both anatase and rutile surfaces are endothermic, except for the dissociative reaction on the rutile surface. The energy levels of the  $\text{BCl}_x$  reactions between the anatase and rutile surfaces show that the rutile surface has lower energy levels than those of anatase surface. This result reveals that the  $\text{BCl}_x$  dissociative adsorption more easily occurs on rutile surface than on anatase surface.

## Introduction

$\text{TiO}_2$  is a very versatile and robust material which has been employed for many industrial applications, such as photocatalysis<sup>1,2</sup> and solar energy conversion by means of photoelectrochemical water splitting<sup>3</sup> or photoelectric conversion by photovoltaics, which have been pioneered by Graetzel and co-workers<sup>1,4-7</sup> for their dye-sensitized solar cells using nanoparticle films of  $\text{TiO}_2$ . In that system, dye sensitizers are strongly bonded chemically with the  $\text{TiO}_2$  substrate by the carboxyl group,  $-\text{C}(\text{O})\text{O}-$ .

For a similar solar cell fabrication, we have succeeded in depositing InN thin films by OMCVD (organometallic chemical vapor deposition) on  $\text{TiO}_2$  nanoparticles with  $\text{HN}_3$  and trimethyl indium;<sup>8</sup> the results exhibit a broad UV/vis-absorption around 390–800 nm. To enhance the electron transfer from InN to  $\text{TiO}_2$ , various chemical linking groups<sup>9,10</sup> forming strong bonding between the sensitizer and the metal oxide substrate are being investigated. Among them,  $-\text{B}(\text{O})\text{O}-$ , which may be produced by the reaction of  $\text{BCl}_x$  with  $\text{TiO}_2$ , is believed to have a rather strong binding with  $\text{TiO}_2$  and may potentially bond with the N atom in the InN film. Practically,  $\text{BCl}_x$  species can be generated readily in plasma by microwave or radio frequency discharge, for example. B is a typical p-doping material in use by the semiconductor industry.

In this study, the binding configurations and energies of  $\text{BCl}_x$  ( $x = 0-3$ ) on the most stable titania surfaces, anatase (101) and rutile (110), have been predicted by first-principles calculations. The result of the present study to be presented below indeed shows very strong bonding between  $\text{BCl}_x$  ( $x < 3$ ) and  $\text{TiO}_2$  on both surfaces. However, the potential energy surfaces

show that the  $\text{BCl}_x$  dissociative reactions on both surfaces are mostly endothermic due to the strong B–Cl bonds.

## Computational Model and Method

Figure 1a,b shows the structures of  $\text{TiO}_2$  anatase (101) and rutile (110) surfaces. The larger gray atoms and smaller red atoms represent the Ti and O atoms, respectively. The anatase and rutile  $\text{TiO}_2$  surfaces have similar structures in that both have the 2- and 3-fold-coordinated O atoms and 5- and 6-fold-coordinated Ti atoms, labeled as 2c-O, 3c-O, 5c-Ti and 6c-Ti, respectively. It has been shown that these two surfaces have lower energies with similar characteristics<sup>11</sup> and may coexist in nanoparticle films. The 2-fold-coordinated O and 5-fold-coordinated Ti atoms are more active because the lower-coordination of these atoms bind more strongly with adsorbates.

The slab model is adopted to simulate the interaction between the  $\text{TiO}_2$  surface and  $\text{BCl}_x$  species. The super cells employed for both  $\text{TiO}_2$  anatase and rutile calculations contain 16 [ $\text{TiO}_2$ ] units. In the direction perpendicular to the super cell, a vacuum space is imposed for the surface reaction as well as to ensure no interaction with the lowest layer of the upper slab. The lowest layer of the super cell is fixed in calculation to prevent surface deformation.

The geometrical structures are optimized by Vienna ab initio Simulation Package (VASP),<sup>12-15</sup> implementing the density functional theory. The generalized gradient approximation (GGA)<sup>16,17</sup> used for the total energy calculations is that of Perdew–Wang 1991 (PW91) formulation.<sup>16</sup> The core pseudopotentials supplied by VASP are used for the present calculation. The ten 3p, 3d, and 4s electrons of each Ti atom and the six 2s and 2p electrons of each O atom are explicitly considered. For the periodic condition, the electronic orbitals are expanded by a plane-wave basis set. The plane wave expansion includes all plane waves with their kinetic energies smaller than the chosen cutoff energy,  $\hbar^2 k^2 / 2m < E_{\text{cut}}$ , which ensures the convergence

with respect to the basis set. The Brillouin zone is sampled with the chosen Monkhorst-Pack<sup>18</sup>  $k$ -points, which also ensures the convergence of the whole system.

## Results and Discussion

**a. Verification.** Verifications on the correctness and accuracy of the model adopted herein have been carried out. The bulk properties and adsorption reactions for both  $\text{TiO}_2$  anatase and rutile surfaces are computed to verify the calculation parameters. The model size  $3 \times 2 \times 1$  is adopted along the three primitive vector directions for anatase, the Monkhorst-Pack  $k$ -points is set as  $1 \times 2 \times 2$ , and the  $E_{\text{cut}}$  set as 600 eV. The lattice constant obtained for the anatase crystal are  $a = 3.805 \text{ \AA}$  and  $c = 9.798 \text{ \AA}$ , which agree well with the X-ray diffraction results of  $a = 3.785 \text{ \AA}$  and  $c = 9.514 \text{ \AA}$ .<sup>19</sup> The lattice constant obtained from the bulk calculation is applied to the surface models with a 10  $\text{\AA}$  vacuum space. The adsorption energy of water on  $\text{TiO}_2(101)$  was predicted to be 14.3 kcal/mol, which falls in the experimental range, 11.5–16.1 kcal/mol.<sup>20</sup>

Similarly, the model size of  $1 \times 2 \times 2$  along the three primitive vectors is adopted for the  $\text{TiO}_2$  rutile structure. The Monkhorst-Pack  $k$ -points is set as  $3 \times 3 \times 2$ , and the value of  $E_{\text{cut}}$  is set as 600 eV. The lattice constant obtained for the rutile crystal found are  $a = 4.659 \text{ \AA}$  and  $c = 2.985 \text{ \AA}$ , which agree well with the X-ray diffraction results of  $a = 4.593 \text{ \AA}$  and  $c = 2.933 \text{ \AA}$ .<sup>21</sup> The adsorption energy of  $\text{H}_2\text{O}$  on the 5c-Ti was predicted to be 18.4 kcal/mol, which also agrees well with the literature value of 20.9 kcal/mol.<sup>22,23</sup> Finally, the bond length

**TABLE 1: Comparison of Bond Length and Bond Angle for  $\text{BCl}_x$ ,  $x = 1-3$ , Calculated by VASP and Gaussian 03**

	$r(\text{B}-\text{Cl}1)$	$r(\text{B}-\text{Cl}2)$	$r(\text{B}-\text{Cl}3)$	$-\text{ClBCl}$

of the gas-phase molecule of  $\text{BCl}_3$  and its fragments are calculated by VASP and compared to the results calculated by Gaussian03<sup>24</sup> as listed in Table 1 for comparison. It is shown that the results obtained by VASP agree well with those obtained by Gaussian03.

**b. Adsorbate Structures on Anatase Surface.** The possible adsorption configurations of  $\text{BCl}_3$  and its fragments on the  $\text{TiO}_2$  anatase (101) surface are shown in Figure 2, and the associated bond lengths and adsorption energies are also listed in Table 2. The adsorbates on the 5-fold-coordinated Ti atoms or the 2-fold-coordinated O atoms are labeled as adsorbate-Ti and adsorbate-O. In Table 2, the two-site adsorbates on either O and O or Ti and O are also included besides the single-site adsorbate on Ti or O. The most stable adsorbate structure for the single-site adsorption configuration is  $\text{Cl}_2\text{B}-\text{O}(a)$  with the adsorption energy of 81.6 kcal/mol and the B–O bond length of 1.341  $\text{\AA}$ , which is the shortest bond length among the single-site adsorbates. For the same adsorbate on Ti,  $\text{Cl}_2\text{B}-\text{Ti}(a)$ , the adsorption energy is only 9.0 kcal/mol, which is far less than that of  $\text{Cl}_2\text{B}-\text{O}(a)$ . In addition, for the  $\text{Cl}_2\text{B}-\text{Ti}(a)$  adsorbate, the B–Ti bond length is 2.766  $\text{\AA}$ , which is much larger than that of  $\text{Cl}_2\text{B}-\text{O}(a)$ . The adsorbates with stronger adsorption energies between B and O atoms than that of B and Ti atoms resulted from the empty p-orbital of B atom, which interacts strongly with the lone pair electrons of the O atom. Similarly, the  $\text{BCl}_3$  gas molecule can only adsorb on the surface O rather than on Ti atoms. One of the three bond lengths of the  $\text{BCl}_3$  adsorbate structure is longer than the other two, i.e.,  $r(\text{B}-\text{Cl}3) > r(\text{B}-\text{Cl}2) > r(\text{B}-\text{Cl}1)$ ; see Table 2. This indicates that the bonding between the third Cl and B atoms is weaker than the other two Cl–B because the B atom is more stable at its 3-fold coordinated.

Five double-site adsorbates are found in the calculation. Two of them are B and  $\text{BCl}$ , adsorbed on both Ti and O sites on the same (010) plane producing  $\text{B}(\text{Ti})\text{O}(a)$  and  $\text{ClB}(\text{Ti})\text{O}(a)$ , respectively. The other two are  $\text{BCl}$  and  $\text{BCl}_2$ , which adsorb across two O sites on two neighboring (010) planes, forming bridge structures  $\text{ClB}(\text{O})\text{O}'(a)$  and  $\text{Cl}_2\text{B}(\text{O})\text{O}'(a)$ , respectively. The fifth involves  $\text{BCl}$ , which adsorbs across a Ti and an O' site forming a double-site adsorbate,  $\text{ClB}(\text{Ti})\text{O}'(a)$ . The adsorption sites of Ti and O located in the same (010) plane will be called in-plane Ti and O herein, as in the former two double-site adsorption configurations. The latter three double-site adsorption configurations, having their adsorption sites located at different (010) planes, will be called bridge Ti and O' here (see Figure 1 for the structures). The adsorption energies for the former two adsorbates on in-plane Ti and O,  $\text{B}(\text{Ti})\text{O}(a)$  and  $\text{ClB}(\text{Ti})\text{O}(a)$ , are 101.2 and 61.0 kcal/mol. Similarly, the adsorption energies for the bridge O site adsorbates,  $\text{ClB}(\text{O})\text{O}'(a)$  and  $\text{Cl}_2\text{B}(\text{O})\text{O}'(a)$ , and adsorbate  $\text{ClB}(\text{Ti})\text{O}'(a)$  for the bridge Ti and O site are 84.2, 78.7, and 39.7 kcal/mol, respectively. The adsorbates of double-site adsorption, either on Ti and O or on O and O', are relatively more stable than the same adsorbates of single-site adsorption. For example, the adsorption energies of double-site adsorbate of  $\text{BCl}$ ,  $\text{ClB}(\text{Ti})\text{O}(a)$  adsorbed on either in-plane or bridge Ti and O' and  $\text{ClB}-$

Figure 2. Possible adsorbate on  $\text{TiO}_2$  anatase (101) surface.

	$r(\text{Ti}(\text{O})-\text{B}(\text{Cl}))$	$r(\text{B}-\text{Cl}1)$	$r(\text{B}-\text{Cl}2)$	$r(\text{B}-\text{Cl}3)$	$E_{\text{ads}}$
$\text{Cl}_2\text{B}-\text{Ti}(\text{a})$	2.766	1.707	1.707		9.0
$\text{ClB}-\text{Ti}(\text{a})$	2.379	1.680			14.8
$\text{Cl}_3\text{B}-\text{O}(\text{a})$	1.460	1.776	1.808	2.076	8.4
$\text{Cl}_2\text{B}-\text{O}(\text{a})$	1.341	1.771	1.751		81.6
$\text{ClB}-\text{O}(\text{a})$	1.469	1.825			11.9
$\text{B}-\text{O}(\text{a})$	1.281				97.8
$\text{Cl}-\text{Ti}(\text{a})$	2.374				17.0
$\text{Cl}-\text{O}(\text{a})$	2.260				2.7
$\text{B}(\text{Ti})\text{O}(\text{a})$	2.299, 1.238				101.2
$\text{ClB}(\text{Ti})\text{O}(\text{a})$	2.210, 1.328	1.734			61.0
$\text{ClB}-(\text{O})\text{O}'(\text{a})$	1.375, 1.384	1.775			84.2
$\text{Cl}_2\text{B}-(\text{O})\text{O}'(\text{a})$	1.469, 1.475	1.871	1.924		78.7
$\text{ClB}(\text{Ti})\text{O}'(\text{a})$	2.689, 1.364	1.758			39.7

$(\text{O})\text{O}'(\text{a})$ , are larger than those of single-site adsorbates,  $\text{ClB}-\text{Ti}(\text{a})$  and  $\text{ClB}-\text{O}(\text{a})$ , as indicated in Table 1. Similarly, the adsorption energy of the double-site adsorbate of the B atom,  $\text{B}(\text{Ti})\text{O}(\text{a})$ , is also larger than that of single-site adsorbate,  $\text{B}-\text{O}(\text{a})$ , by 3.4 kcal/mol. The only one exception is  $\text{Cl}_2\text{B}(\text{a})$ , whose double-site adsorbate  $\text{Cl}_2\text{B}(\text{O})\text{O}'(\text{a})$  is less stable than the single-site adsorbate  $\text{Cl}_2\text{B}-\text{O}(\text{a})$ . This is because the 3-fold-coordinated B atom in  $\text{Cl}_2\text{B}-\text{O}(\text{a})$  has a larger adsorption energy than that of the over-coordinated bonding configuration,  $\text{Cl}_2\text{B}-(\text{O})\text{O}'(\text{a})$ .

Panels a and b of Figure 3 show the detailed structures of  $\text{B}(\text{Ti})\text{O}(\text{a})$  and  $\text{ClB}(\text{Ti})\text{O}(\text{a})$ , respectively. For  $\text{B}(\text{Ti})\text{O}(\text{a})$ , the

$\text{B}-\text{Ti}$  bond, 2.299 Å, is slightly longer than that of  $\text{B}-\text{O}$  bond, 1.238 Å. This again reflects that the B atom is adsorbed more preferably on the O than on the Ti atoms, as mentioned previously. In addition, the surface structure of  $\text{TiO}_2$  also shows the influence by the B adsorbate that the bond lengths for  $\text{O}1-\text{Ti}1$  and  $\text{O}1-\text{Ti}2$  are stretched significantly, from 1.859 and 1.837 Å to 2.223 and 2.506 Å, respectively. The  $-\text{Ti}1\text{O}1\text{Ti}2$  becomes smaller from  $100.6^\circ$  to  $85.1^\circ$  and  $-\text{Ti}2\text{O}2\text{Ti}1$  becomes larger from  $94.8^\circ$  to  $115.0^\circ$ , comparing to those of the bare  $\text{TiO}_2$  surface. The adsorbate structure of  $\text{ClB}(\text{Ti})\text{O}(\text{a})$  is similar to  $\text{B}(\text{Ti})\text{O}(\text{a})$ , where the  $\text{B}-\text{O}$  bond is also shorter than  $\text{B}-\text{Ti}$ . The length of the  $\text{B}-\text{Cl}$  bond is 1.734 Å, which is somewhat smaller than the  $\text{B}-\text{Cl}$  bonds of the equilibrium  $\text{BCl}_3$  in the gas phase, 1.747 Å, and longer than that of the equilibrium  $\text{BCl}$ , 1.723 Å. This result indicates that the bond strength of  $\text{B}-\text{Cl}$  in adsorbate  $\text{ClB}(\text{O})\text{O}'(\text{a})$  lies in between those of  $\text{BCl}$  and  $\text{BCl}_3$  in the gas phase. The influence of the  $\text{TiO}_2$  structure by the adsorption of  $\text{BCl}$  is also similar to the  $\text{B}(\text{a})$  case, except that effect exerted on  $\text{O}1$  and  $\text{Ti}2$  is slightly smaller than that by the B atom. This can be seen from the bond lengths of  $\text{Ti}1-\text{O}1$  and  $\text{Ti}2-\text{O}1$  for the  $\text{BCl}(\text{a})$ , which are shorter than those of  $\text{B}(\text{a})$ , and  $-\text{Ti}2\text{O}1\text{Ti}2$  for  $\text{BCl}(\text{a})$  is larger than that of  $\text{B}(\text{a})$ , and  $-\text{Ti}2\text{BO}1$  is  $69.5^\circ$  for  $\text{BCl}(\text{a})$ , which is smaller than that of  $-\text{Ti}2\text{BO}1$ ,  $84.5^\circ$ , for the  $\text{B}(\text{a})$  case.

Similarly, panels a and b of Figure 4 show the detailed structures of the double-site adsorbates,  $\text{ClB}(\text{O})\text{O}'(\text{a})$ , and  $\text{Cl}_2\text{B}-$

**Figure 3.** Detailed structure of (a)  $\text{B(Ti)O(a)}$ , (b)  $\text{ClB(Ti)O(a)}$ , and (c) bare  $\text{TiO}_2$  anatase surface.

(O)O'(a). For  $\text{ClB-O(a)}$ , the two bond lengths between B and O atoms, B–O1 and B–O2, are 1.384 and 1.375 Å, respectively. The B–Cl bond is 1.775 Å, and  $\text{–O1BO2}$  is  $126.6^\circ$ . The angle of two bridge O are bent inward from an equilibrium angle of  $101.4^\circ$  to  $81.6^\circ$ ,  $\text{–O2Ti1O3}$ , at the left side in the figure, and from  $96.2^\circ$  to  $83.5^\circ$ ,  $\text{–O1Ti2O3}$ , at the right side in the figure, respectively. The distance between these two bridge O atoms, O1–O2, is shorten to 2.464 Å by the binding force of B and 2O. The original distance between these two bridge O atoms is 3.785 Å on the bare surface. In addition, for the  $\text{TiO}_2$  substrate, O2–Ti1 is also stretched from the equilibrium bond length of 1.859 to 2.257 Å, at left side in the figure, and the O1–Ti2 bond length is also stretched from 1.859 to 2.248 Å at right side in the figure.

For  $\text{Cl}_2\text{B(O)O'}$ (a) (see Figure 4b), the bond lengths of the B atom with the two adsorbed O atoms, B–O1 and B–O2, are 1.475 and 1.469 Å, and those of BC11 and BC12 are 1.871 and 1.924 Å, respectively. The angle between B and two O-atom adsorbent  $\text{–O1BO2}$  is  $115.6^\circ$ . In addition, the

**Figure 4.** Detailed structure of (a)  $\text{ClB(O)O'}$  (a), (b)  $\text{Cl}_2\text{B(O)O'}$  (b), and (c) bare  $\text{TiO}_2$  anatase surface.

distance between the two bridge O sites becomes 2.491 Å, which is considerably shorter than its original distance between the two bridge atoms, 3.785 Å, on the  $\text{TiO}_2$  bare surface. Comparing the structures of  $\text{Cl}_2\text{B(O)O'}$ (a) and  $\text{ClB(O)O'}$ (a), all the bond lengths in the former are longer than those in the latter; and the distances between the two adsorption O sites of  $\text{Cl}_2\text{B(O)O'}$ (a) are also longer than those of  $\text{ClB(O)O'}$ (a). This again reveals that the 3-fold-coordinated B atom has a stronger bonding force than that of 4-fold-coordinated ones. Similar to  $\text{ClB(O)O'}$ (a), all the bond lengths between Ti and O atom are also stretched by  $\text{Cl}_2\text{B}$ ; however, the bond length is slightly shorter than those in  $\text{ClB(O)O'}$ (a). Finally, the angles of  $\text{–O2Ti1O3}$  and  $\text{–O1Ti2O3}$  are both equal to  $84.1^\circ$ , which are

**Figure 5.** Detailed structure of (a)  $\text{ClB(Ti)O}'$  (a) and (b) bare  $\text{TiO}_2$  anatase surface.

larger than those of the related angles in  $\text{ClB(a)}$ ,  $81.6^\circ$  and  $83.5^\circ$ , respectively.

Figure 5 shows the detailed configuration of  $\text{BCl}$  adsorbed on the bridge  $\text{O}'$  and  $\text{Ti}$  atoms,  $\text{ClB(Ti)O}'$ (a). The  $\text{B-Ti}$  bond is  $2.689 \text{ \AA}$ , the  $\text{B-O}$  bond is  $1.364 \text{ \AA}$ , and  $-\text{O1BTi1}$  is  $117.4^\circ$ . Both of  $\text{B-Ti}$  and  $\text{B-O}$  bonds are longer than those  $\text{B(Ti)O(a)}$  and  $\text{ClB(Ti)O(a)}$ , where the adsorption sites,  $\text{Ti}$  and  $\text{O}$ , are located at in-plane positions. This is because the adsorption geometry for  $\text{ClB(Ti)O}'$ (a) is more constrained than those in  $\text{B(Ti)O(a)}$  and  $\text{ClB(Ti)O(a)}$ . This is also the reason why the adsorption energy of  $\text{ClB(Ti)O}'$ (a) on bridge  $\text{Ti}$  and  $\text{O}$  is smaller than those of  $\text{B(Ti)O(a)}$  and  $\text{ClB(Ti)O(a)}$  on in-plane  $\text{Ti}$  and  $\text{O}$ . The  $\text{O1-Ti1}$  with  $3.530 \text{ \AA}$  in  $\text{ClB(Ti)O}'$ (a) adsorbed on bridge  $\text{Ti}$  and  $\text{O}'$  has been shortened by  $0.49 \text{ \AA}$  compared to the  $\text{O1-Ti1}$  on the bare  $\text{TiO}_2$  surface,  $4.020 \text{ \AA}$ .

Finally, the adsorption energies for the  $\text{Cl}$  adsorbate on  $\text{Ti}$  and  $\text{O}$  sites,  $\text{Cl-Ti(a)}$  and  $\text{Cl-O(a)}$ , are  $17.0$  and  $2.7 \text{ kcal/mol}$  and their bond lengths are  $2.374$  and  $2.260 \text{ \AA}$ , respectively. Thus, the  $\text{Cl}$  atom adsorbs more preferably on the  $\text{Ti}$  atom than on the  $\text{O}$  atom. This is because the  $\text{Cl}$  atom prefers to donate the lone pair electron to  $\text{Ti}$  than to the electron-rich  $\text{O}$  site.

**c. Adsorbate Structure on Rutile Surface.** The possible adsorbate structures of  $\text{BCl}_3$  and its fragments on the rutile (110) surface are shown in Figure 6, and the related bond lengths and adsorption energies are listed in Table 3. Similar to the results for adsorption on the anatase (101) surface presented above, both single-site and double-site adsorption structures are also found on the rutile surface. Among single-site adsorbates,  $\text{Cl}_2\text{B-O(a)}$  is the most stable, with an adsorption energy of  $103.8 \text{ kcal/mol}$  and a  $\text{B-O}$  bond length of  $1.354 \text{ \AA}$ . In addition, similar to that on the anatase surface,

**TABLE 3: Bond Length and Adsorption Energy of Possible Adsorbate on  $\text{TiO}_2$  Rutile (110) Surface**

	$r(\text{Ti(O)-B(Cl)})$	$r(\text{B-Cl1})$	$r(\text{B-Cl2})$	$r(\text{B-Cl3})$	$E_{\text{ads}}$

$\text{Cl-O(a)}$	1.677				17.3
$\text{ClB(O)O(a)}$	1.385, 1.385	1.760			124.8
$\text{Cl}_2\text{B(O)O(a)}$	1.542, 1.542	1.821	1.821		92.8
$\text{ClB(Ti)O'(a)}$	2.469, 1.324	1.735			70.7

the  $\text{BCl}_3$  molecule can directly adsorb on an  $\text{O}$  atom. The adsorption energy of  $\text{Cl}_3\text{B-O(a)}$  is  $8.7 \text{ kcal/mol}$ , which is slightly larger than that of  $\text{Cl}_3\text{B-O(a)}$  on the anatase surface. The  $\text{B-O}$  is  $1.462 \text{ \AA}$ , and the  $\text{B-Cl1}$ ,  $\text{B-Cl2}$ , and  $\text{B-Cl3}$  bonds are almost equal to  $1.8 \text{ \AA}$ . This is different from  $\text{Cl}_3\text{B-O(a)}$  on the anatase surface, in which one of its  $\text{B-Cl1}$  bonds is shorter than the other two due to the stronger interaction of the particular  $\text{Cl1}$  atom than the other two  $\text{Cl2}$  and  $\text{Cl3}$  atoms (Table 2), showing that the three  $\text{Cl}$  atoms are not homogeneously adsorbed on the  $\text{B}$ . This reveals that the  $\text{O}$  site on the rutile surface is more reactive than the same  $\text{O}$  site on the anatase surface.

The other single-site adsorbates involve  $\text{B}$  and  $\text{Cl}$  on  $\text{Ti}$  and  $\text{O}$  atoms, giving  $\text{B-Ti(a)}$ ,  $\text{B-O(a)}$ ,  $\text{Cl-Ti(a)}$ , and  $\text{Cl-O(a)}$ . The predicted adsorption energies show that  $\text{B}$  preferably adsorbs on the  $\text{O}$  rather than the  $\text{Ti}$  sites. Their adsorption energies are  $121.3 \text{ kcal/mol}$  for  $\text{B-O(a)}$  and  $21.6 \text{ kcal/mol}$  for  $\text{B-Ti(a)}$ . This trend is similar to that observed on the anatase surface. Finally, the adsorption energies for the  $\text{Cl}$  atom on the  $\text{Ti}$  and  $\text{O}$  atoms are  $31.9$  and  $17.3 \text{ kcal/mol}$ , respectively. These are similar to the results on the anatase surface as aforementioned.

There are three adsorbates with double-site adsorption found for  $\text{BCl}$  and  $\text{BCl}_2$  on the bridge  $\text{O}$  atoms,  $\text{ClB(O)O(a)}$  and  $\text{Cl}_2\text{B(O)O(a)}$ , and  $\text{BCl}$  on the bridge  $\text{Ti}$  and  $\text{O}$  atoms,  $\text{ClB(Ti)O}'$ (a). The adsorbates of  $\text{ClB(O)O(a)}$  and  $\text{Cl}_2\text{B(O)O(a)}$  have  $124.8$  and  $92.8 \text{ kcal/mol}$  adsorption energies, respectively, are located on the same  $(\bar{1}01)$  plane, whereas the adsorbate  $\text{ClB(Ti)O}'$ (a) with  $70.7 \text{ kcal/mol}$  adsorption energy is located on different  $(\bar{1}01)$  planes. Among three double-site adsorbates,  $\text{ClB(Ti)O}'$ (a) is the smallest. The trend of the adsorption energies is similar to that on the anatase surface, more energy is required to overcome the geometry constraint arising from long separation between the  $\text{Ti}$  and  $\text{O}$  sites.

Figure 7(a) and 7(b) show the adsorbate structures of  $\text{ClB}$  and  $\text{Cl}_2\text{B}$  on  $\text{TiO}_2$  rutile (110). The bond lengths between  $\text{B}$  and the two bridge  $\text{O}$  atoms in  $\text{ClB(O)O(a)}$  are  $1.385 \text{ \AA}$  and that in  $\text{Cl}_2\text{B(O)O(a)}$  is  $1.542 \text{ \AA}$ . In addition,  $\text{B-Cl}$  is  $1.760 \text{ \AA}$  in  $\text{ClB(O)O(a)}$  and is  $1.821 \text{ \AA}$  in  $\text{Cl}_2\text{B(O)O(a)}$ . The angle between  $\text{B}$  and two bridge  $\text{O}$  is predicted to be  $116.8^\circ$  in  $\text{ClB(O)O(a)}$  and is  $106.4^\circ$  in  $\text{Cl}_2\text{B(O)O(a)}$ . In addition, the bond lengths between  $\text{Ti1}$  and  $\text{O1}$  are  $2.162$  and  $1.988 \text{ \AA}$  for  $\text{ClB(a)}$  and  $\text{ClB}_2$ (a), respectively. The  $\text{Ti1-O1}$  in  $\text{ClB(a)}$  being smaller than that in  $\text{Cl}_2\text{B(a)}$ , the  $\text{B-O1}$  in  $\text{ClB(O)O(a)}$  being smaller than that in  $\text{Cl}_2\text{B(O)O(a)}$ , and the  $-\text{O1BO2}$  in  $\text{ClB(a)}$  being larger than that in  $\text{Cl}_2\text{B(a)}$  reflects that  $\text{BCl(a)}$  has a stronger bonding force.

Figure 8 shows the adsorbate structure of  $\text{ClB(Ti)O}'$ (a) on the  $\text{TiO}_2$  rutile surface and the bare surface for comparison. The computed  $\text{B-Ti}$  and  $\text{B-O}$  are  $2.469 \text{ \AA}$  and  $1.324 \text{ \AA}$ ,

Figure 6. Possible adsorbate on  $\text{TiO}_2$  rutile (110) surface.

respectively. The B–Cl and –Ti2BO1 in ClB(a) are 1.735 Å and 109.7°, respectively. The structure change of the  $\text{TiO}_2$  surface shows that the surface O site is bent inward to form ClB(Ti)O'(a). The –O1Ti1O2 is changed from 90.4° to 79.3°. The original distance of O1–T2 is shortened from 3.563 to 3.171 Å due to the binding forces of B–O and B–Ti. Finally, the change of Ti1–O1 also reveals that the bridge O atom is slightly pulled up by bonding between B and O. The Ti1–O1 bond length is changed from 1.843 Å of the bare surface to 2.139 Å in the ClB(Ti)O(a).

**d. Potential Energy Diagram  $\text{BCl}_x$  Adsorbates on Anatase Surface.** Figure 9a shows the potential energy diagram for the dissociative adsorption of  $\text{BCl}_x$ ,  $x = 1-3$ , on the anatase surface. The adsorption energies are similar to  $\text{BCl}_3(\text{g})$  and the  $\text{TiO}_2$  anatase (101) surface. The dissociative adsorption of  $\text{BCl}_3$  on the surface is highly endothermic, except for the initial molecular adsorption of  $\text{BCl}_3(\text{a})$ . There are two possible dissociation pathways from  $\text{BCl}_3(\text{a})$ , producing  $\text{Cl}_2\text{B}-\text{O}(\text{a})$  or  $\text{Cl}_2\text{B}(\text{O})\text{O}'(\text{a})$ . As discussed above, the latter is less stable than the former. The dissociated Cl atom can be adsorbed on either Ti or O atoms. The dissociated adsorbates of  $\text{Cl}_2\text{B}-\text{O}(\text{a}) + \text{Cl}-\text{Ti}(\text{a})$  are formed with the lowest energy of 25.8 kcal/mol.

Following the second Cl dissociation from  $\text{BCl}_2$ , the energy level is elevated because more energy is required to dissociate the second B–Cl bond, which is not compensated by the increase in the adsorption energy of BCl and the additional adsorption energy of the Cl atom. There are three double-site adsorptions of BCl, ClB(Ti)O(a) adsorbed on either in-plane or bridge, Ti and O, ClB(O)O'(a), as alluded to before and similar to the previous case, the dissociated Cl can be adsorbed on either Ti or O atoms. Thus, in total there are three possibilities for adsorption of the two dissociated Cl atoms: on two Ti, Ti and O, and two O atoms. From the three double-site adsorbates, there are in total nine different energy products. Among these nine dissociated states, the energetically most stable one is the ClB(a) doubly adsorbed on bridge O atoms, with the two dissociated Cl atoms individually adsorbed on two Ti sites, ClB(O)O'(a) + 2Cl-Ti(a); its adsorption energy is 89.2 kcal/mol above  $\text{BCl}_3(\text{g}) + \text{anatase (101)}$ . The next lowest state is BCl(a) doubly adsorbed on the O atoms with the two Cl atoms adsorbing on O and Ti sites individually. The adsorption energy of this adsorbate is 104.1 kcal/mol. Finally, the third lowest state (+112.5 kcal/mol) is the two dissociated Cl adsorbing on both two O sites. Other higher energy adsorbates, or less stable dissociative products, are given in Figure 9a.

**Figure 7.** Detailed structure of (a) ClB(O)O(a), (b) Cl<sub>2</sub>B(O)O(a), and (c) bare TiO<sub>2</sub> rutile surface.

**e. Potential Energy Diagram of Adsorbates on Rutile Surface.** Similarly, Figure 9b shows the potential energy diagram of BCl<sub>x</sub>(a) on the TiO<sub>2</sub> rutile (110) surface. As in the anatase surface, the dissociative adsorption of BCl<sub>3</sub> on the rutile surface is also highly endothermic; however, the energies for the dissociation of the second and third Cl atoms are not so high as the analogous reactions on the anatase surface. In addition, the initial adsorption of Cl<sub>3</sub>B(a) on an O site, giving Cl<sub>3</sub>B–O(a), and its dissociation products of Cl<sub>2</sub>B–O(a)+Cl–Ti(a) are exothermic. These two energies are –8.7 and –10.8 kcal/mol, respectively.

Unlike the anatase case, only two adsorbates, ClB(O)O(a) and ClB(Ti)O'(a), are formed from the dissociation of Cl<sub>2</sub>B–O(a). Thus, six different products could be formed with the two dissociated Cl atoms adsorbing on either Ti or O atoms. Among these products, the most stable one is the BCl(a) adsorbed on the bridge O atoms with the two dissociated Cl atoms individually adsorbing on Ti atoms, ClB(O)O(a) + 2Cl–Ti(a). The total energy of these products is 19.9 kcal/mol above the reactants, BCl<sub>3</sub>(g) + rutile (110) surface.

**f. Overall Comparison for BCl<sub>3</sub> Reaction on the Anatase and Rutile Surface.** In terms of adsorption configurations, there are very similar adsorbates both the TiO<sub>2</sub> anatase and rutile surfaces. For single site adsorbates on anatase and rutile surfaces, the slight difference is found, in which B atom can be weakly adsorbed on Ti atom forming B–Ti(a) on the rutile surface,

**Figure 8.** Detailed structure of (a) ClB(Ti)O'(a) and (b) bare TiO<sub>2</sub> rutile surface.

though not on the anatase surface. This results from their structure characteristics of the sawtooth-anatase surface with the 2-fold-coordinated O and 5-fold-coordinated Ti and the flat-rutile surface with 2-fold-coordinated and 5-fold-coordinated Ti.<sup>11</sup> On the anatase surface, the O and Ti site are close (~1.8 Å) and at the in-plane position so that the B cannot singly adsorb on only Ti atom without the influence of the strong adsorption by the O atom. On the rutile surface, the O and Ti sites are rather far away (3.6 Å); therefore, B can be adsorbed on the Ti atom without the strong influence of by the neighboring O atom. Furthermore, the difference in double-site adsorptions between the anatase and rutile surfaces is similar. There are five double-site adsorbates found for the anatase surface and only three for rutile surface. The additional two double-site adsorbates of B(Ti)O(a) and ClB(Ti)O(a) for the anatase are due to the two very close Ti and O sites located at in-plane positions, where B and BCl can easily be adsorbed on these in-plane Ti and O atoms, as indicated above for the B atom adsorption.

Comparing with the adsorption energies of all the adsorbates for both anatase and rutile surfaces, the B atom is adsorbed more preferably on the O than Ti atoms. On the other hand, Cl atom is more preferably adsorbed on the Ti atom. Comparing adsorption energy of the single-site adsorbate, both O and Ti sites of rutile are more active than those of anatase attributable to the difference in surface structures.

Finally, both potential energy surfaces show that BCl<sub>3</sub> can adsorb on the O site of both anatase and rutile surfaces, and most of the BCl<sub>x</sub> fragments behave similarly. The dissociative adsorptions of BCl<sub>3</sub>, on both surfaces are endothermic, except only for one reaction involving BCl<sub>3</sub> and rutile. Comparing the energetics of the BCl<sub>x</sub> reactions between two surfaces, rutile is more reactive and produces more stable adsorbates.

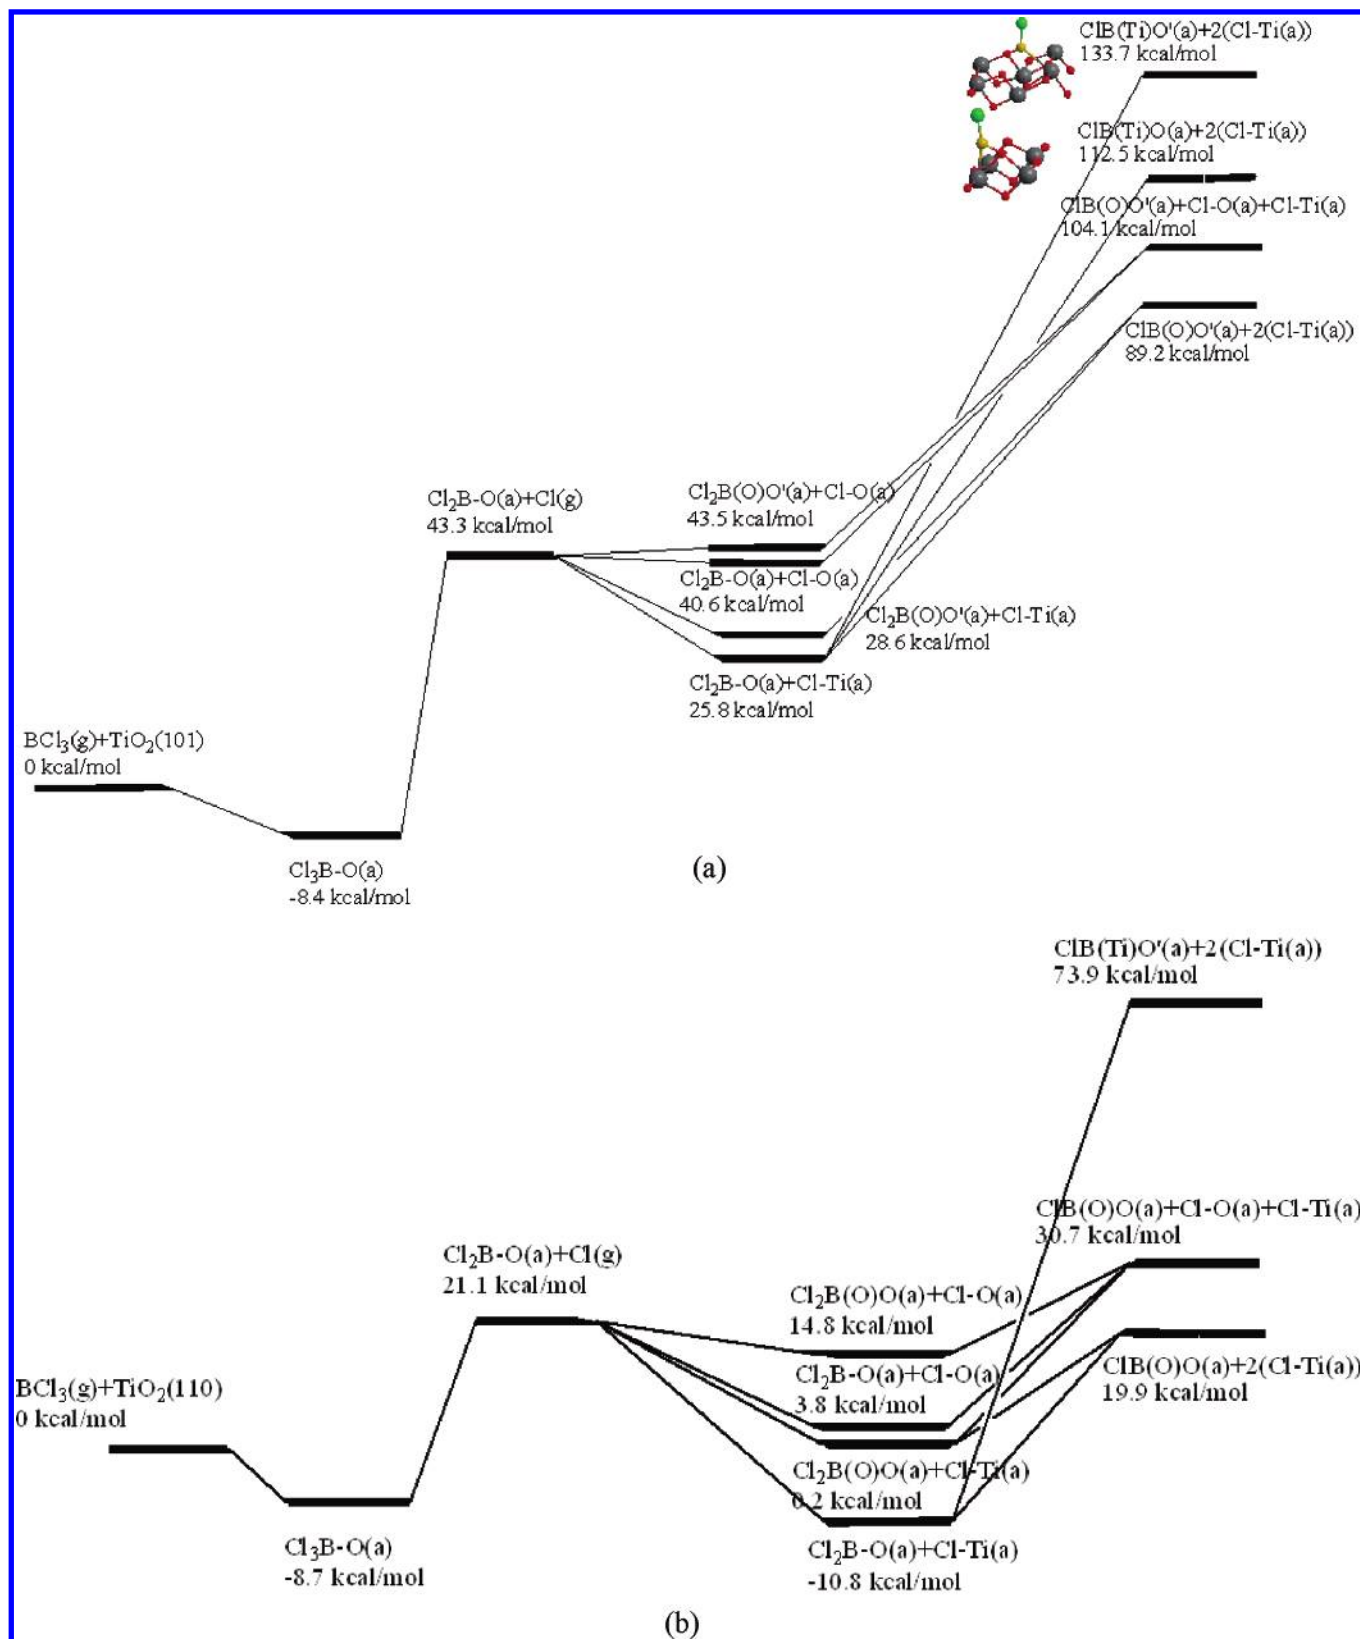

Figure 9. Potential energy surface of  $\text{BCl}_x$  on (a)  $\text{TiO}_2$  anatase surface and (b)  $\text{TiO}_2$  rutile surface.

## Conclusion

This study investigates the adsorption and reaction of  $\text{BCl}_3$  and its fragments on the  $\text{TiO}_2$  anatase (101) and rutile (110) surfaces by first-principles calculations based on the DFT with GGA and the plane-wave method. The results show that the possible absorption configurations in both surfaces are very

similar. Small differences were found due to the difference in the surface structures between anatase (101) and rutile (110). On the anatase surface the binding between B and Ti is negligibly weak. The potential energy surface shows that  $\text{BCl}_3$  can be adsorbed on the O site on both surfaces, and starting from  $\text{BCl}_3$ , the formation of  $\text{BCl}_x(\text{a})$  is endothermic. The  $\text{BCl}_x$

reactions on the rutile surface have lower endothermicities than those on the anatase surface, reflecting the predicted stronger binding energies for  $\text{BCl}_x$  on the rutile surface. However, the energy barriers for the dissociation of  $\text{BCl}_x$  ( $x = 1-3$ ) to smaller fragments are quite high. To functionalize  $\text{TiO}_2$  with  $\text{BCl}_x$  species one needs plasma or UV irradiation, for example.
