Received: August 21, 2006; In Final Form: November 9, 2006

Kinetics and mechanisms for NH₃ reactions with ClO_x (x = 0–4) radicals have been investigated at the G2M level of theory in conjunction with statistical theory calculations. The geometric parameters of the species and stationary points involved in the reactions have been optimized at the B3LYP/6-311+G(3df,2p) level of theory. Their energetics have been further refined with the G2M method. The results show that the H-abstraction process is the most favorable channel in each reaction and the barriers predicted in decreasing order are OClO > ClO > Cl > ClO₃ > ClO₄. All reactions were found to occur by hydrogen-bonding complexes; the rate constants for these complex metathetical processes have been calculated in the temperature range 200–2000 K by the microcanonical VTST and/or RRKM theory (for ClO₄ + NH₃) with Eckart tunneling and multiple reflection corrections. The predicted rate constants are in good agreement with the available experimental data.

I. Introduction

The reactions of NH₃ with chain-carriers such as ClO_x (x = 0–4) radicals play a pivotal role in the propulsion kinetics of the systems containing ammonium perchlorate (AP), a widely used propellant at present.¹ These reactions may also be relevant to the chemistry of stratosphere and the explosion caused by ammonium perchlorate at the Pacific Engineering and Production Company (PEPCON) facility,² where some of these species are present.

In 1974, Clyne and Watson³ studied mass spectrometrically the kinetics of rapid bimolecular reactions involving ClO (X²Π, *v* = 0) radicals at 298 K using molecular beam sampling from a discharge-flow system. They found that the ClO radical is unreactive toward a range of singlet ground state molecules up to 670 K and estimated that the upper limit for the NH₃ + ClO rate constant at 670 K is 1 × 10⁻¹⁵ cm³ molecule⁻¹ s⁻¹. In 1977, Westenberg and DeHaas⁴ reported their measurement for the NH₃ + Cl → NH₂ + HCl reaction with the rate constant of 1.23 × 10⁻¹³ cm³ molecule⁻¹ s⁻¹ at 298 K and 19.6–43.8 Torr argon pressure by the flash photolysis–resonance fluorescence technique. Recently, Gao et al.⁵ measured the rate constant for Cl + NH₃ → HCl + NH₂ over 290–570 K by the time-resolved resonance fluorescence technique. The rate constant was fitted by the expression $k(\text{NH}_3 + \text{Cl}) = (1.08 \pm 0.05) \times 10^{-11} \exp[-(2.74 \pm 0.04 \text{ kcal mol}^{-1})/RT]$ cm³ molecule⁻¹ s⁻¹. They also characterized the potential energy surface of this reaction with the composite G3B3, CBS-QB3, and MPWB1K density functional theory. To our knowledge, no other measurements nor theoretical studies on the kinetics and mechanisms for the ClO_x radical reactions with NH₃ have been reported. These reactions are in fact very relevant to the understanding and simulation of AP propulsion chemistry.

In the present study, the G2M method⁶ has been employed to investigate the five reaction systems of NH₃ + ClO_x (x =

0–4), and their rate constants were also calculated and compared with the available experimental values.

II. Computational Methods

The geometric parameters of the species and stationary points related to the title reactions were optimized at the B3LYP/6-311+G(3df,2p) level of theory,⁷ and their vibrational frequencies were also calculated at this level. For more accurate evaluation of the energetic parameters, higher-level single-point energy calculations of the stationary points were carried out by the modified Gaussian-2 (G2M) theory,⁶ based on the optimized geometries at the B3LYP/6-311+G(3df,2p) level of theory. The G2M(CC2) method calculates the base energy at the PMP4/6-311G(d,p) level of theory and improves it with the expanded basis set and coupled cluster corrections as well as a “higher level correction (HLC)”. All ab initio calculations were carried out with Gaussian 03 program.⁸

The rate constants for the five reactions were calculated by the VARIFLEX code⁹ based on the microcanonical variational transition state (VTST) or Rice–Ramsperger–Kassel–Marcus (RRKM) theory¹⁰ for processes which occur by stable intermediates. The component rates were evaluated at the E/J-resolved level, and the pressure dependence was treated by one-dimensional master equation calculations using the Boltzmann probability of the complex for the J-distribution. For the barrierless association/decomposition process, the fitted Morse function, $V(R) = D_e\{1 - \exp[-\beta(R - R_e)]\}^2$, was used to represent the minimum potential energy path (MEP) as will be discussed later. Here, *D_e* is the bonding energy excluding zero-point vibrational energy for an association reaction, *R* is the reaction coordinate (i.e., the distance between the two bonding atoms), and *R_e* is the equilibrium value of *R* at the stable intermediate structure. For the ClO₄ + NH₃ reaction which occurs via two rather deep prereaction and postreaction complexes (vide infra), we have also employed the ChemRate code of Mokrushin et al.¹¹ to corroborate the predicted rate constant by the Variflex program.⁹

III. Results and Discussion

A. Mechanisms of $\text{NH}_3 + \text{ClO}_x$ ($x = 0-4$) Reactions. The optimized geometries of the intermediate complexes and transition states at the B3LYP/6-311+G(3df,2p) level of theory are shown in Figure 1; all their Cartesian coordinates and vibrational frequencies are placed in Table S1 of the Supporting Information. The vibrational frequencies and moments of inertia of reactants and some of their intermediate complexes and transition states used in the rate constant calculation are listed in Table 1. The potential energy diagrams of the five reactions, obtained at the G2M/B3LYP/6-311+G(3df,2p) level of theory, are presented in Figure 2. Otherwise stated, all the energies cited below are the G2M values relative to those of the reactants. In addition, the spin-orbit correction, -0.83 kcal/mol, is included for the Cl atom¹² in the potential energy diagram for the $\text{NH}_3 + \text{Cl}$ reaction.

$\text{NH}_3 + \text{Cl}$. As shown in Figures 1 and 2, there are two possibilities for Cl atom to attack the NH_3 molecule. In the first case, Cl approaches the side of the H atoms in NH_3 to form an $\text{NH}_3 \cdots \text{Cl}$ hemibonded complex (LM1) with C_{3v} symmetry; the Cl-H separation is 2.595 Å. LM1 lies 3.6 kcal/mol below the reactants; it can eliminate an HCl molecule via TS1 with a 7.8 kcal/mol barrier above LM1. On the product side, another

H-bonded complex $\text{H}_2\text{N} \cdots \text{HCl}$ (LM2) was located, which is 4.0 kcal/mol lower than the final products, $\text{NH}_2 + \text{HCl}$. Also, at the B3LYP/6-311+G(3df,2p) level of theory, the energy of LM1 is 12.0 kcal/mol below that of reactants, which is 8.4 kcal/mol greater than that at the G2M level. This extra stability may be caused by overestimating the electron correlation energy of the hemibonded complex by the density functional theory. In the second case, Cl approaches the N atom of NH_3 to form a more stable intermediate complex $\text{Cl} \cdots \text{NH}_3$ (LM3) with the binding energy of 7.1 kcal/mol and the Cl-N bonding distance of 2.432 Å. However, the further decomposition of LM3 to $\text{NH}_2\text{-Cl} + \text{H}$ needs to pass TS2 with a much higher potential barrier of 48.7 kcal/mol.

From Figure 2, the heats of reaction for the formation of $\text{NH}_2 + \text{HCl}$ and $\text{NH}_2\text{Cl} + \text{H}$ are predicted to be 4.6 and 46.8 kcal/mol, respectively. On the basis of the heats of formation for NH_3 , NH_2 , Cl, HCl, and H tabulated by Chase¹³ in 1998, the heat of reaction of $\text{NH}_3 + \text{Cl} \rightarrow \text{NH}_2 + \text{HCl}$ is 4.8 ± 1.5 kcal/mol. The predicted value lies within the experimental error range. Also, on the basis of the two values of the heat of formation of NH_2Cl given by Livett et al.,¹⁴ 17.7 kcal/mol (obtained from 16 kcal/mol at 298 K based on the heats of formation of NH_2^+ and Cl) and 13.7 kcal/mol (obtained from

12 kcal/mol at 298 K using bond energy data obtained in their experiment) at 0 K, the heats of reaction for NH₃ + Cl → H + NH₂Cl are estimated to be 50.0 and 46.0 kcal/mol, respectively.

Our predicted value is 3.2 kcal/mol less than the former and is 0.8 kcal/mol higher than the latter. It is thus reasonable to employ the G2M method for elucidation and prediction of the kinetics and mechanisms of the NH₃ + ClO_x reactions.

Comparing the PES of NH₃ + Cl, the geometric parameters of the transition state and complexes are basically in agreement with those optimized by Gao et al.⁵ at the MPWB1K/6-31+G-(2df,2p) level of theory, and the energies of TS1, LM2, and LM3 are 2.5, 1.1, and 4.4 kcal/mol higher than theirs, respectively. However, they did not report the structure of the entrance complex (LM1) for the NH₂ + HCl channel.

NH₃ + ClO. In this reaction, there are two possible reaction channels as shown in Figure 2. The first one is hydrogen atom abstraction from NH₃ by oxygen atom of ClO via a hydrogen-bond complex ClO...HNNH₂ (LM4) and transition state (TS3) to another H-bonding complex ClOH...NH₂ (LM5) is predicted to have a binding energy of 1.3 kcal/mol, and TS3 and LM5 lie above the reactants at 13.2 and 4.1 kcal/mol, respectively. The complex ClOH...NH₂ can therefore easily decompose to the products NH₂ + HOCl followed by H...N bond breaking. Although LM5 can connect with the products NH₂Cl + HO via TS4 with Cl atom attacking N atom, their formation is not expected to be important because of the much higher barrier of TS4 (36 kcal/mol).

The second reaction channel is the approaching of the O atom of ClO toward the N atom of NH₃ via TS5 with the Cl–O bond lengthening concertedly to give the complex LM6. The potential barrier of this step is 28.4 kcal/mol, which is greater than that of TS3 by 15.2 kcal/mol. LM6 is a four-membered ring structure with both weak Cl–O and Cl–H bonds. So, the Cl atom can be eliminated directly from LM6 to form NH₃O + Cl. In addition, the HCl molecule can be formed exothermically from LM6 via a much lower barrier at TS6, 4.3 kcal/mol above LM6 or 15.2 kcal/mol above the ClO + NH₃ reactants. This direct NH₃ oxidation process cannot compete with the H-abstraction reaction producing HOCl in view of the high barrier at TS5.

NH₃ + OClO. Both reactants NH₃ and OClO can first form a four-membered ring complex (LM7) with 2.7 kcal/mol binding energy; the complex has a loose structure because of the long O...H and Cl...N separations in LM7 (see Figure 1). LM7 can undergo H-abstraction reaction via TS7 with a 30.5 kcal/mol barrier to form the complex H₂N...HOCIO (LM8) and, in principle, can also undergo O-abstraction by NH₃ directly producing NH₃O + ClO via TS9 with a much higher barrier of

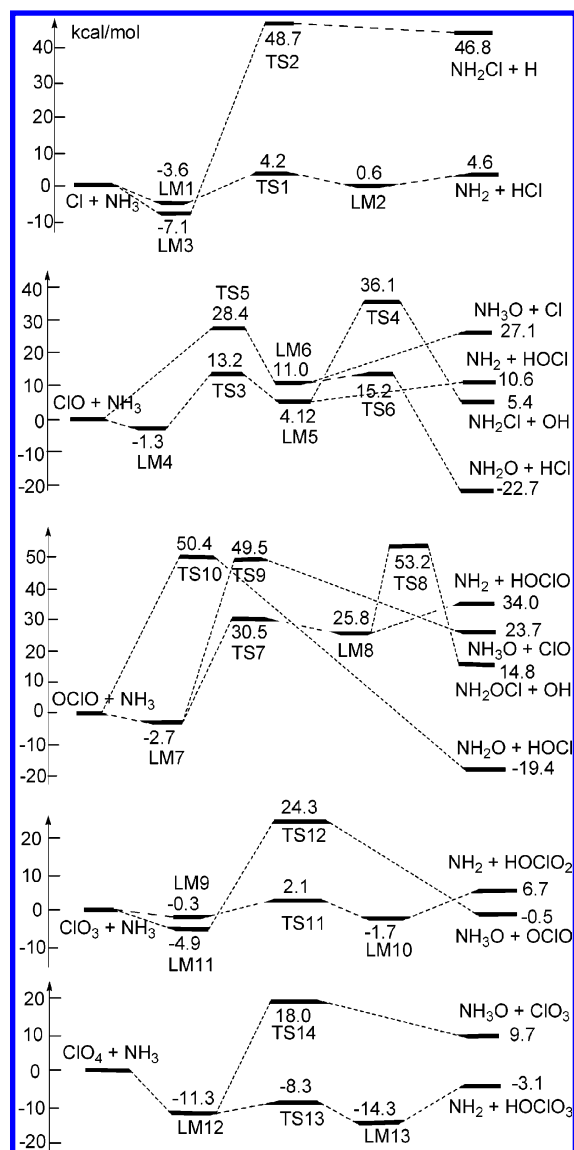

Figure 2. Schematic energy diagrams (in kcal/mol units) computed at the G2M/B3LYP/6-311+G(3df,2p) level of theory.

49.5 kcal/mol. The latter process apparently cannot compete with the former due to its high barrier. LM8 is an N \cdots H hydrogen-bonded complex lying slightly below TS7; it can dissociate readily to NH₂ + HOClO and, in principle, also to NH₂OCl + OH via a very high barrier at TS8, 53.2 kcal/mol, by a concerted dual-bond breaking process. In addition, a five-membered ring transition state TS10 can directly connect the reactants NH₃ + OClO with the lowest energy products NH₂O + HOCl. The potential barrier of TS10, 50.4 kcal/mol, is much higher than that of TS7 (30.5 kcal/mol), however, although it is the most exothermic process ($\Delta H = -19.4$ kcal/mol) in the system.

NH₃ + ClO₃. Similar to the NH₃ + Cl reaction, two prereaction complexes can be formed by H–O and N–Cl bondings giving LM9 and LM11, respectively. Both have C_{3v} structures with energies slightly below the reactants by 0.3 and 4.9 kcal/mol, respectively, as shown in Figure 2. From LM9, the shortening of one of the three H \cdots O bonds with the concurrent lengthening of the associated H–N bond at TS11 gives rise to the H-abstraction product LM10, an N \cdots H-bonding complex, H₂N \cdots HOClO₂. LM10 can further fragment to produce the final products NH₂ + HOClO₂ with an overall 6.7 kcal/mol endothermicity. The energy of TS11 is 2.1 kcal/mol while that of LM10 is -1.7 kcal/mol. This H-abstraction reaction can take place readily.

Another reaction channel is from LM11 to products NH₃O + OClO via the oxygen abstraction transition state TS12 with a 24.3 kcal/mol barrier. Because TS12 is about 12 times greater than TS11 in energy, this redox process is kinetically irrelevant.

NH₃ + ClO₄. Because of the C_{2v} symmetry of ClO₄ in the ground electronic state (²B₁), it can only form one intermediate complex (LM12) with NH₃ as seen in Figure 2. The prereaction complex has a 11.3 kcal/mol binding energy. Similar to the NH₃–ClO₂ system, both H- and O-abstraction reactions can ensue from LM12. H-abstraction occurs via TS13 to give a stable H₂N \cdots HOClO₃ complex (LM13, -14.3 kcal/mol below the reactants) and the final products NH₂ + HOClO₃. Because of the small abstraction barrier and the high stabilities of both LM12 and LM13, TS13 lies below the reactants by as much as 8.3 kcal/mol, or 3.0 and 6.1 kcal/mol above LM12 and LM13, respectively. The reaction producing NH₂ + HOClO₃ is exothermic ($\Delta H = -3.1$ kcal/mol), and it can take place readily.

The barrier for O-transfer from ClO₄ to NH₃ via TS14 is 18.0 kcal/mol, which is much greater than that for the H-abstraction process. Thus, the direct oxidation of NH₃ to NH₃O by ClO₄ is unimportant.

From the above discussions of the five reaction mechanisms, we can conclude that H-abstraction is the most favorable path in each reaction; the amidogen radical (NH₂) is therefore the main product in this series of reactions. Comparing the reaction barriers for all the H-abstraction channels, the following decreasing order with OClO > ClO > Cl > ClO₃ > ClO₄ is observed. Also, from the five N \cdots H hydrogen-bonding complexes, LM2, LM5, LM8, LM10, and LM13, the N \cdots H bond energies are predicted to be 4.0, 6.5, 8.2, 8.4, and 11.3 kcal/mol, respectively. Obviously, the N \cdots H bond strengths increase with the number of oxygen atoms in HClO_x ($x = 0-4$). At the B3LYP/6-311+G(3df,2p) level of theory, the Mulliken atomic charge of N in NH₂ is $-0.386e$ while those of Cl in HCl, HOCl, HOClO, HOClO₂, and HOClO₃ are $-0.220e$, $0.029e$, $0.528e$, $0.968e$, and $1.714e$, respectively. Accordingly, the variation in the N \cdots H bond strengths may be attributed to the atomic charges of Cl in HClO_x. The more positive the Mulliken atomic charge

TABLE 2: Morse Parameters for Association/Dissociation Processes of the Hydrogen Abstraction Channels

reaction	D _e /kcal/mol	β/Å ⁻¹	R _e /Å
LM1 → NH ₃ + Cl	4.4	1.654	2.595
LM2 → NH ₂ + ClO	6.0	1.423	1.890

of Cl in HClO_x is, the stronger the N \cdots H bond in the complex H₂N \cdots HClO_x becomes.

B. Rate Constant Calculations. As discussed in the above section, the hydrogen abstractions from NH₃ by ClO_x ($x = 0-4$) take place by complex-forming metathetical mechanisms involving H-bonding prereaction and postreaction intermediates:

The rate constants of these processes were calculated by microcanonical VTST and RRKM theory (for reaction 5), and the contributions from other channels are reasonably neglected. The VTST calculations were carried out with the unified statistical formulation of Miller¹⁵ including both tunneling and multiple reflection corrections¹⁶ above the shallow wells of the prereaction and postreaction complexes. For the RRKM calculations, the L-J (Lennard-Jones) parameters were taken to be $\sigma = 3.47$ Å and $\epsilon/k = 114$ K for argon buffer gas from the literature¹⁷ and $\sigma = 4.20$ Å and $\epsilon/k = 230$ K approximately for the intermediate complexes from our previous paper¹⁸ on the HOClO molecular intermediate. The minimum energy paths (MEPs) for barrierless association and dissociation processes occurring without intrinsic transition states were optimized at the B3LYP/6-311+G(3df, 2p) level of theory by manually varying the key coordinates point by point for complex formation from the reactants or products. They were fitted to Morse functions to approximately represent the MEPs of the association/dissociation processes. The Morse parameters are summarized in Table 2.

As indicated above, the Eckart tunneling corrections¹⁹ have been made for rate constants of the H-abstraction reactions at low temperatures. However, only NH₃ + ClO and NH₃ + ClO₃ reactions have noticeable tunneling effects because of their larger imaginary frequencies, 1519 cm⁻¹ at TS3 and 1170 cm⁻¹ at TS11. Their rate constants with Eckart tunneling corrections are 91.9% and 37.3% larger at 300 K for the former and latter processes, respectively. For the NH₃ + Cl reaction the correction only increases its rate constant by 1.2% at 300 K because of the smaller imaginary frequencies, 319 cm⁻¹ at TS1. The tunneling effects on the other two reactions are negligibly small.

The effects of multiple reflections above the complex-wells predicted with Miller's method¹⁵ show that the rate constants for H-abstraction reactions by ClO, OClO, and ClO₄ are reduced by 44.8%, 172.0%, and 59.5%, respectively, at 300 K. The rate constant of NH₃ + Cl was decreased by only 17.6%, and that

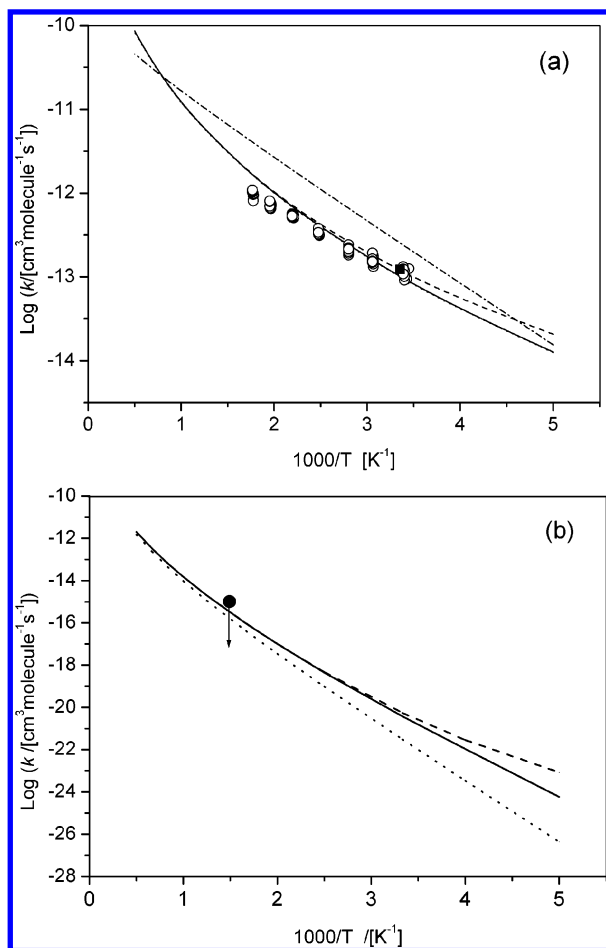

Figure 3. Predicted rate constants with multiple reflection and tunneling corrections comparing with the experimental data: (a) $k(\text{NH}_3 + \text{Cl})$, (b) $k(\text{NH}_3 + \text{ClO})$. Solid line indicates rate constant with multiple reflection and tunneling effects. Dashed line indicates rate constant without multiple reflections. Dotted line indicates rate constant without tunneling corrections. Solid circle reflects ref 3. Solid square reflects ref 4. Open circle reflects experimental data from ref 5. Dashed-dotted line shows theoretical data from ref 5.

of $\text{NH}_3 + \text{ClO}_3$ was not affected at 300 K. These effects stem primarily from the multiple reflections above the wells of postreaction complexes as their H-abstraction transition states are closer to the exit variational barriers leading to product formation. The effects of multiple reflection and tunneling corrections for the rate constants of the $\text{NH}_3 + \text{Cl}$ and ClO reactions are shown in Figure 3. As shown in the figure, both tunneling and multireflection effects diminish gradually with increasing temperature.

In addition, the small-curvature effect^{20a} on the reaction path of the smallest system, $\text{NH}_3 + \text{Cl}$, via the transition state TS1 was included to correct the hydrogen transfer rate constant. The small-curvature correction factors were predicted to be 3.99 and 1.62 at 300 and 500 K, respectively; the effect disappears at high temperatures. It can also be ignored in larger reaction systems.

Figure 4 compares the rate constants of these five reactions in the temperature range 200–2000 K. All rate constants have small positive temperature dependence and exhibit no pressure effect, except that for the $\text{NH}_3 + \text{ClO}_4$ reaction which has a small negative temperature dependence with a minor pressure effect at low temperatures above 100 atm. Because of the existence of the large pre- and postreaction complexes in this reaction, we have also performed rate constant calculations at 300, 500, 800, and 1000 K temperatures using the ChemRate

Figure 4. Predicted rate constants for five hydrogen abstraction reactions. Solid line shows $k(\text{NH}_3 + \text{Cl})$. Dashed line shows $k(\text{NH}_3 + \text{ClO})$. Dotted line shows $k(\text{NH}_3 + \text{OCIO})$. Dashed-dotted line indicates $k(\text{NH}_3 + \text{ClO}_3)$. Dashed-double-dotted line indicates $k(\text{NH}_3 + \text{ClO}_4)$.

TABLE 3: Comparison of Predicted Rate Constants k_C (by ChemRate Program) and k_V (by Variflex Program) in $\text{cm}^3 \text{molecule}^{-1} \text{s}^{-1}$ for Reaction 5: $\text{ClO}_4 + \text{NH}_3 \leftrightarrow \text{LM12} \leftrightarrow \text{TS13} \leftrightarrow \text{LM13} \rightarrow \text{NH}_2 + \text{HOClO}_3$

T (K)	k_C	k_V
300	2.44×10^{-9}	3.09×10^{-9}
500	1.32×10^{-9}	1.49×10^{-9}
800	3.51×10^{-10}	5.16×10^{-10}
1000	2.44×10^{-10}	3.78×10^{-10}

code¹¹ for comparison with the values predicted by Variflex.⁹ The variational transition states for the barrierless association/decomposition processes were determined by the canonical variational method.^{16a,20} The results of these calculations summarized in Table 3 indicated that the agreement in the values obtained by both methods is quite good.

The predicted individual rate constants at atmospheric pressure in units of $\text{cm}^3 \text{molecule}^{-1} \text{s}^{-1}$ can be expressed as

$$k(\text{NH}_3 + \text{Cl}) = 9.11 \times 10^{-19} T^{2.47} \exp(-726/T)$$

$$k(\text{NH}_3 + \text{ClO}) = 1.87 \times 10^{-24} T^{3.85} \exp(-4344/T)$$

$$k(\text{NH}_3 + \text{OCIO}) = 1.48 \times 10^{-20} T^{3.05} \exp(-15657/T)$$

$$k(\text{NH}_3 + \text{ClO}_3) = 1.36 \times 10^{-14} T^{1.01} \exp(-2255/T)$$

$$\begin{aligned} k(\text{NH}_3 + \text{ClO}_4) &= 8.44 \times 10^{-1} T^{-3.02} \exp(-528/T) \\ &\quad (200-1000 \text{ K}) \\ &= 2.34 \times 10^{-20} T^{2.80} \exp(4392/T) \\ &\quad (1000-2000 \text{ K}) \end{aligned}$$

As mentioned in the Introduction, there are two experimental rate constant data available for the $\text{NH}_3 + \text{Cl}$ reaction: $k(\text{NH}_3 + \text{Cl}) = 1.23 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K, reported by Westenberg and DeHaas,⁴ and the expression $k(\text{NH}_3 + \text{Cl}) = (1.08 \pm 0.05) \times 10^{-11} \exp[-(2.74 \pm 0.04 \text{ kcal mol}^{-1})/RT] \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the temperature range 290–570 K, reported by Gao et al.⁵ As mentioned previously, Gao et al.⁵ also evaluated the theoretical rate constants from the PES calculated at the MPWB1K/6-31+G(2df,2p) level of theory. Figure 3a compares these data with our predicted result. Our predicted rate constants are in good agreement with the experimental data below 500 K with a small deviation noted at higher

temperatures. The theoretical prediction by Gao et al. is, however, 2 times greater than their experimental values.

For the $\text{NH}_3 + \text{ClO}$ reaction, only one experimental rate constant, $k(\text{NH}_3 + \text{ClO}) \leq 1 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, describes an upper limit of the rate constant at 670 K by Clyne and Watson.³ The value predicted at 670 K for this reaction, $3.04 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, is consistent with the experimental upper limit. For the $\text{ClO}_4 + \text{NH}_3$ reaction, the exceptionally large rate constant at low temperatures (see Table 3) results from the unique combination of the following factors: (1) the high attractive potential between ClO_4 and NH_3 (the $\text{H}_3\text{N} \cdots \text{OCIO}_3$ complex has a very large dipole moment of 6.1362 D), (2) all the transition states involved in the reaction lie below the reactants, resulting in a downhill slide from the reactants to the products ($\text{NH}_2 + \text{HOClO}_3$), and (3) the large reaction path degeneracy, 12, for the abstraction reaction.

We believe that the above rate constants for the $\text{NH}_3 + \text{ClO}_x$ ($x = 0 - 4$) reactions are reasonable and may be employed for computer modeling of propellant combustion involving AP with a high degree of reliability within the temperature range specified.

IV. Conclusions

The mechanisms for a series of reactions of NH_3 with ClO_x ($x = 0 - 4$) radicals have been studied at the G2M//B3LYP/6-311+G(3df,2p) level of theory in conjunction with statistical rate-theory calculations. The results of these calculations show that the H-abstraction process is the most favorable low-energy reaction channel in each of these reactions, and the predicted barriers in declining order are $\text{OCIO} > \text{ClO} > \text{Cl} > \text{ClO}_3 > \text{ClO}_4$. Their rate constants have been calculated in temperature range 200–2000 K by microcanonical VTST and/or RRKM theory with Eckart tunneling and multiple-reflection corrections. The results of the calculations indicate that the tunneling effects on both $\text{NH}_3 + \text{ClO}$ and ClO_3 reactions are significant, and the effects of multiple reflections above the wells of H-bonding complexes, primarily the postreaction complexes, in the NH_3 reactions with ClO , OCIO , and ClO_4 at low temperatures are noticeable. The predicted results (for Cl and ClO reactions) are basically in agreement with available experimental data.
