Abstract. A general method for the analysis of frequency -modulation reticles is **Abstract.** A general method for the analysis of frequency-modulation reticles is presented. The formulation starts by introducing the spoke function f(ρ) as an offsetting factor to the phase angle θ . Through the process of coordinate transformation, the output signal after demodulation is obtained. The result transformation, the output signal after demodulation is obtained. The result contains two main parts: the first part represents the contribution from the contains two main parts: the first part represents the contribution from the basic configuration of a straight -edge spoke; the second part, containing the basic configuration of a straight-edge spoke; the second part, containing the term df/d ρ , represents the modifying effect of changing the spoke edge to an arbitrary curve. By means of four examples, the method is shown to be valid in arbitrary curve. By means of four examples, the method is shown to be valid in verifying the dependence of the output signal on the spoke shape. Any verifying the dependence of the output signal on the spoke shape. Any frequency -modulation reticle can be analyzed by this general method so long as frequency-modulation reticle can be analyzed by this general method so long as its corresponding spoke function is known. its corresponding spoke function is known.

Subject terms: optical tracking; frequency -modulation reticles; spoke shape. Subject terms: optical tracking; frequency-modulation reticles; spoke shape.

1. INTRODUCTION **1. INTRODUCTION**

Reticles^{1,2} used in optical trackers or seekers as an element to modulate the light from a remote target can produce signals modulate the light from a remote target can produce signals representing the target's deviation from the optical axis of the mate tracker. The performance of a reticle depends mainly on the tracker. The performance of a reticle depends mainly on the type of modulation and the geometrical shape of its spoke. In $= b/$ this paper we present a general method to analyze the signal this paper we present a general method to analyze the signal produced by frequency -modulation (FM) reticles with spokes produced by frequency-modulation (FM) reticles with spokes of arbitrary shape. of arbitrary shape.

2. MATHEMATICAL FORMULATION **2. MATHEMATICAL FORMULATION**

Consider an FM reticle with 2m equally spaced spokes of $r(r)$ alternating transmittance 1 and 0. Figure 1(a) shows the alternating transmittance 1 and 0. Figure l(a) shows the configuration of such a reticle in operation. The spoke shape configuration of such a reticle in operation. The spoke shape is described by the function $f(\rho)$, which introduces offsetting of the phase angle θ at various radial distances ρ , as shown in Fig. 1(b). Fig. l(b).

The light from the target is focused on the image plane as a The light from the target is focused on the image plane as a spot P, rotating with a constant angular velocity Ω around Ω_1 . The reticle is fixed on this plane. The center of the reticle, The reticle is fixed on this plane. The center of the reticle, which is at O, in general does not coincide with O_1 .

Referring to the O-X-Y coordinate system first, we assume $\mathbb{R}^{(1)}$ that the intensity transmittance function of the reticle is $r(x)$

Paper 2352 received Nov. 3, 1986; revised manuscript received Feb. 4, 1988; Paper 2352 received Nov. 3, 1986; revised manuscript received Feb. 4, 1988; accepted for publication Feb. 4, 1988; received by Managing Editor Feb. 8, accepted for publication Feb. 4, 1988; received by Managing Editor Feb. 8, 1988. 1988.

CONTENTS and the intensity distribution function of the image is $p(x, t)$. The intensity behind the reticle is 1. Introduction The intensity behind the reticle is

$$
u(t) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} r(x) p(x, t) d^2 x
$$
 (1)

For a tiny spot it is reasonable to assume that $p(x, t)$ is a delta function of x; i.e., delta function of x; i.e.,

$$
p(x,t) = \delta(x-x')\delta(y-y') , \qquad (2)
$$

where x'(t) and y'(t) are the instantaneous positional coordi-where x'(t) and y'(t) are the instantaneous positional coordinates of the image spot. nates of the image spot.

For the function $\mathbf{r}(\mathbf{x})$, notice in Fig. 1(a) that $[\theta - \mathbf{f}(\rho)]/2\pi$ = b/ m. Here b stands for a noninteger parameter that takes *=* b/m. Here b stands for a noninteger parameter that takes different values in different spoke zones. For example, in the different values in different spoke zones. For example, in the zone OAB, we have $0 \le b \le 1/2$; in OBC, $1/2 \le b \le 1$; in ODC, $1 \leq b < 3/2$; in ODE, $3/2 \leq b < 2$, ..., and in the last zone, m $-1/2 \le b <$ m. Thus, we have

$$
r(\mathbf{x}) = STP\big(\sin\{m[\theta - f(\rho)]\}\big) \tag{3}
$$

where where

$$
STP(w) = \begin{cases} 1, & w \ge 0, \\ 0, & w < 0. \end{cases}
$$
 (4)

Substituting Eq. (3) into Eq. (1), we have Substituting Eq. (3) into Eq. (1), we have

$$
u(t) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} STP(\sin{\{m[\theta - f(\rho)]\}}) \delta(x - x') \delta(y - y') dxdy
$$

= STP(\sin{\{m[\theta - f(\rho)]\}})
= STP[\sin(\text{argument})] . (5)

Fig. 1. (a) Reticle system. (b) Arbitrary spoke function. **Fig. 1. (a) Reticle system, (b) Arbitrary spoke function.**

After FM demodulation, the electric output voltage is After FM demodulation, the electric output voltage is

$$
v(t) = \frac{d}{dt} \text{ (argument)}
$$

= $m \left[\frac{d\theta}{dt} - f'(\rho) \frac{d\rho}{dt} \right].$ (6)

This signal is then used for control to perform a tracking ϵ_{max} mission in the sense that v(t) approaches a constant. mission in the sense that v(t) approaches a constant.

To work out Eq. (6), we transfer to the $O_1 - X_1 - Y_1$ coordinate system. Using the relationships nate system. Using the relationships

$$
\theta = \tan^{-1} \left(\frac{y}{x} \right) \tag{7}
$$

$$
\rho = \sqrt{x^2 + y^2} \tag{8}
$$

 $x = r_2 \cos \Omega t - r_1 \cos \theta_1$,

 $y = r_2 \sin \Omega t - r_1 \sin \theta_1$,

and introducing them into Eq. (6), we have and introducing them into Eq. (6), we have

$$
v(t) = m\Omega \left\{ 1 + \sum_{n=1}^{\infty} \left(\frac{r_1}{r_2} \right)^n \cos[n(\Omega t - \theta_1)] - \frac{df}{d\rho} \frac{1}{\rho} r_1 r_2 \sin(\Omega t - \theta_1) \right\}.
$$
 (10)

3. EXAMPLES **3. EXAMPLES**

Reticles of different spoke shapes can be examined by apply-Reticles of different spoke shapes can be examined by applying different values of f in Eq. (10). Each yields a correspond-ing different values of f in Eq. (10). Each yields a corresponding value for v(t). ing value for v(t).

3.1. Straight -edge spoke **3.1. Straight-edge spoke**

For a straight -edge spoke, the simplest geometry, there is no For a straight-edge spoke, the simplest geometry, there is no angular variation with respect to ρ , so we assign $f(\rho) = \epsilon_1 =$ const, obtaining const, obtaining

$$
v(t) = m\Omega \left\{ 1 + \sum_{n=1}^{\infty} \left(\frac{r_1}{r_2} \right)^n \cos[n(\Omega t - \theta_1)] \right\} .
$$
 (11)

Readers interested in this case may refer to Suzuki³ and Anderson and Callary.4 Figure 2 shows our result for such a Anderson and Callary.4 Figure 2 shows our result for such a reticle, its spoke function, and its typical output signal v(t). reticle, its spoke function, and its typical output signal v(t).

3.2. Spiral -edge spokes **3.2. Spiral-edge spoke ⁵**

(9)

If we assign $f(\rho) = \epsilon_2 \rho$ for the spoke shape, we have a reticle with spiral -edge spokes, as shown in Fig. 3. The electric out-with spiral-edge spokes, as shown in Fig. 3. The electric output is put is

$$
v(t) = m\Omega \left\{ 1 + \sum_{n=1}^{\infty} \left(\frac{r_1}{r_2} \right)^n \cos[n(\Omega t - \theta_1)] - \frac{\epsilon_2 r_1 r_2 \sin(\Omega t - \theta_1)}{\sqrt{r_1^2 + r_2^2 - 2r_1 r_2 \cos(\Omega t - \theta_1)}} \right\}.
$$

3.3. Parabolic spiral -edge spoke 3.3. Parabolic spiral-edge spoke

If we assign f(ρ) = $\epsilon_3 \rho^2$ for the spoke shape, we have a reticle ϵ_2 with parabolic spiral-edge spokes, as shown in Fig. 4. The $\frac{2}{6}$ output is output is

$$
v(t) = m\Omega \left\{ 1 + \sum_{n=1}^{\infty} \left(\frac{r_1}{r_2} \right)^n \cos[n(\Omega t - \theta_1)] - 2\epsilon_3 r_1 r_2 \sin(\Omega t - \theta_1) \right\}.
$$
 (13)

3.4. Complicated spiral -edge spoke 3.4. Complicated spiral-edge spoke

If we assign $f(\rho) = \epsilon_4 \sin \rho$ for the spoke shape, we have a reticle with complicated spiral-edge spokes, as shown in Fig. 5. The output is output is

$$
v(t) = m\Omega \left\{ 1 + \sum_{n=1}^{\infty} \left(\frac{r_1}{r_2} \right)^n \cos[n(\Omega t - \theta_1)] - \frac{\cos[r_1^2 + r_2^2 - 2r_1r_2\cos(\Omega t - \theta_1)]^{1/2}}{[r_1^2 + r_2^2 - 2r_1r_2\cos(\Omega t - \theta_1)]^{1/2}} \times \epsilon_4 r_1 r_2 \sin(\Omega t - \theta_1) \right\}.
$$
 (14)

4. CONCLUSION **4, CONCLUSION**

A general method is introduced for analyzing the signal pro-A general method is introduced for analyzing the signal produced, after demodulation, by an FM reticle. Since the spoke duced, after demodulation, by an FM reticle. Since the spoke shape varies from reticle to reticle, the dependence of the shape varies from reticle to reticle, the dependence of the output signal on spoke geometry is evident. For the reduced output signal on spoke geometry is evident. For the reduced
